(54) A process for preparing a raw material for milk chocolate.

(57) The invention relates to a process for preparing a raw material for milk chocolate, which comprises kneading and drying a concentrated mixture of milk, sugar and optionally cocoa mass to form a homogeneous mass, and is characterized in that the mixture of condensed milk, sugar and optionally cocoa mass is kneaded and dried in a continuous process step under a vacuum for a period of time of 2-4 hours, said mixture being maintained at a temperature ranging from 45°C to not more than 105°C during said kneading and drying step. It is preferred that said kneading and drying step is carried out in phases, the temperature of said mixture being increased phasewise. The invention leads to very uniform crumb and block milk products of an excellent flavour and colour.

Title: A process for preparing a raw material for milk chocolate

This invention relates to a process for preparing a raw material for milk chocolate, which comprises kneading and drying a concentrated mixture of milk, sugar and optionally cocoa mass to form a homogeneous mass.

5 In the chocolate processing industry milk chocolate is prepared using milk constituents to which sugar and, if desired, cocoa mass are added.

The composition of the ingredients is often so chosen that only cocoa butter and emulsifiers are required 10 for arriving at the composition of milk chocolate. This particularly applies to the mixture which, in addition to milk constituents and sugar, also contains cocoa mass. In dried form this mixture is generally designated as 'crumb'. If the cocoa mass is omitted from the mixture, 15 the dried product is called 'block milk'.

In the preparation of crumb and block milk products are formed having a characteristic flavour. This is achieved during the preparation as a result of maillardization and/or caramelization.

20 The chocolate processing industry imposes strict requirements on the flavour and the appearance of crumb and block milk because these products considerably determine the 'flavour and colour aspect' of the final product.

A problem occurring in the preparation of crumb 25 and block milk is that it is very difficult to arrive at a uniform product, the flavour and colour of which satisfy the requirements imposed. In other words, the flavour and colour development should be controllable without basically affecting the drying process.

30 One of the solutions that were found in the past is to modify the recipe of the crumb and the block

-2-

milk. This has the drawback that a final composition is obtained which is not desired by the chocolate processing industry. Another possibility to arrive at the solution of the above problem is to carry out partial processes 5 outside the actual crumb and block milk preparation. For instance, sugar can be caramelized in dry form by applying a so-called dry-heating process at a temperature of 180-210°C. It is further known to heat a sugar solution at a temperature of 120-160°C. The caramelized sugar (solution) is then 10 mixed with the other crumb or block milk components and processed further. This process, however, is very laborious and therefore uneconomical.

Finally, attempts have been made to affect the maillardization by adding amino acids (preferably lysine) and reducing sugars (mostly glucose). Given a specific process the control possibility is in the dosage 15 of these components. This use, however, gives no sufficient guarantee that the contemplated result is obtained.

The object of this invention therefore is to manufacture crumb or block milk products that are uniform, and the flavour and colour of which are controllable, starting from a given composition. Surprisingly, it has turned out that this object is achieved by continuously carrying out the manufacturing process under a very mild 20 temperature regime in conjunction with a critical duration and under vacuum conditions.

According to the invention a concentrated mixture of milk, sugar and optionally cocoa mass is kneaded and dried in a continuous process step under a vacuum for 25 a period of time of 2-4 hours, said mixture being maintained at a temperature ranging from 45°C to not more than 105°C during said kneading and drying step.

According to a preferred embodiment the kneading and drying step is carried out in phases, the temperature 30 of said mixture being increased phasewise.

According to another preferred embodiment the

kneading and drying step is carried out in three phases, said mixture being maintained at a temperature of 45-65°C during the first phase, at a temperature of 65-90°C during the second phase and at a temperature of 90-105°C during 5 the third phase. Finally, it is preferred to carry out the whole process under a pressure of 5-16 kPa.

The advantages of the process according to the invention are as follows:

- a. an excellent flavour and colour development 10 due to the homogeneous treatment of kneading and drying under the imposed conditions during a prolonged process;
- b. the kneading treatment leads to a high free fat content, which is favourable to the chocolate production.

The process will be illustrated by the following 15 examples.

Example 1

To 100 l pasteurized (18 sec., 85°C) and standard- ized (3.0% fat) milk, 10.7 kg sugar were added and dissolved with stirring. This milk/sugar mixture was condensed by 20 means of a vacuum circulation evaporator which resulted in 34.1 kg thickened product having a moisture content of 32%.

This concentrated product was continuously fed, at a temperature of 56°C, to a horizontal cylindrical 25 drum in which is mounted a horizontal shaft with blades and product guides, said shaft being driven by an electric motor, thus ensuring a continuous kneading effect and a horizontal product transport through the cylinder. To increase the kneading effect, scraper hooks are mounted 30 on the inner wall of the drum in various places. The whole cylinder is provided with a heating jacket and can be vacuumized. The cylinder is provided with two overflow weirs dividing the cylinder in three equal sections.

At a process pressure of about 8 kPa the product 35 was heated to respectively 50°C (first section), 73°C (second section) and 92°C (third section) and thus dried.

-4-

with kneading to form a powder having a final moisture content of 2.5%, a sugar content of 45.0% and a fat content of 12.6%. The total process time was 2.5 hours.

This powder was cream light-brown in colour,
5 had a very characteristic slightly caramelized flavour,
contained 1,920 mg/kg hydroxymethylfurfural (HMF) which
indicates a certain degree of maillardization, and had
a free fat content of 11.7%. The powder had a very homoge-
neous appearance, without dark-coloured dots or other
10 inhomogeneities.

After addition of cocoa mass, cocoa butter
and lecithin this powder could be properly processed to
a milk chocolate, which was distinguished by an excellent
flavour and by the fact that, because of the high free
15 fat content, relatively little cocoa butter was additionally
necessary for adjusting the required viscosity of the
chocolate mass for pouring into moulds.

Following Example 2
To 30.000 l pasteurized (14 sec, 76°C) and
20 standardized (3.25% fat) milk 4,590 kg sugar were added
and dissolved with stirring.

This mixture of milk and sugar was condensed
in the manner usual in the dairy industry by means of
a vacuum downdraught evaporator which resulted in 11,800
25 kg concentrate having a moisture content of 28.1%.

This concentrate was mixed with 930 kg cocoa
mass (50% fat) and supplied to an apparatus as described
in Example 1 at a temperature of 49°C. At a process pressure
of about 15 kPa the product was heated to respectively
30 62°C (first section), 85°C (second section) and 104° (third
section) and was thus dried to form a powder having a
moisture content of 1.7%, a sugar content of 47.1%, a
fat content or free fat content of 14.9 or 13.1% (the
milk fat content is 10.1%), a HMF content of 1,450 mg/kg
35 and having an attractive red brown colour, a quite homoge-
neous appearance and a very characteristic flavour.

0248462

-5-

This 'crumb' could be properly processed with cocoa butter and lecithin to form a milk chocolate distinguished by an excellent flavour. In the preparation of this milk chocolate the cocoa butter consumption was relatively low.

CLAIMS

1. A process for preparing a raw material for milk chocolate, which comprises kneading and drying a concentrated mixture of milk, sugar and optionally cocoa mass to form a homogeneous mass, characterized in that
5 the mixture of condensed milk, sugar and optionally cocoa mass is kneaded and dried in a continuous process step under a vacuum for a period of time of 2-4 hours, said mixture being maintained at a temperature ranging from 45°C to not more than 105°C during said kneading and drying
10 step.
2. A process according to claim 1, characterized in that said kneading and drying step is carried out in phases, the temperature of said mixture being increased phasewise.
- 15 3. A process according to claim 2, characterized in that said kneading and drying step is carried out in three phases, said mixture being maintained at a temperature of 45-65°C during the first phase, at a temperature of 65-90°C during the second phase and at a temperature of
20 90-105°C during the third phase.
4. A process according to claims 1-3, characterized in that it is carried out under a pressure of 5-16 kPa.
